

# The Skeptic's Case

Who Are You Going To Believe – The Government Climate Scientists Or The Data?

Guest Post Dr David M.W. Evans

We check the main predictions of the climate models against the best and latest data. Fortunately the climate models got all their major predictions wrong. Why? Every serious skeptical scientist has been consistently saying essentially the same thing for over 20 years, yet most people have never heard the message — here it is, put simply enough for any lay reader willing to pay attention.

## What the Government Climate Scientists Say

Figure 1: The climate models. If the CO<sub>2</sub> level doubles (as it is on course to do by about 2070 to 2100), the climate models estimate the temperature increase due to that extra CO<sub>2</sub> will be about  $1.1^{\circ}\text{C} \times 3 = 3.3^{\circ}\text{C}$ . [1]

The direct effect of CO<sub>2</sub> is well-established physics, based on laboratory results, and known for over a century. [2]

Feedbacks are due to the ways the Earth reacts to the direct warming effect of the CO<sub>2</sub>. The threefold amplification by feedbacks is based on the assumption, or guess, made around 1980, that more warming due to CO<sub>2</sub> will cause more evaporation from the oceans and that this extra water vapor will in turn lead to even more heat trapping because water vapor is the main greenhouse gas. And extra heat will cause even more evaporation, and so on. This amplification is built into all the climate models. [3] The amount of amplification is estimated by assuming that nearly all the industrial-age warming is due to our CO<sub>2</sub>.

The government climate scientists and the media often tell us about the direct effect of the CO<sub>2</sub>, but rarely admit that two thirds of their projected temperature increases are due to amplification by feedbacks. They [admit there are discrepancies](#), and go to great lengths to [resolve them](#) (see for example, [Thorne](#), [Dessler](#), [Sherwood](#)).

## What the Skeptics Say

Figure 2: The skeptic's view. If the CO<sub>2</sub> level doubles, skeptics estimates that the temperature increase due to that extra CO<sub>2</sub> will be about  $1.1^{\circ}\text{C} \times 0.5 \approx 0.6^{\circ}\text{C}$ .[\[4\]](#)

The serious skeptical scientists have always agreed with the government climate scientists about the direct effect of CO<sub>2</sub>. The argument is entirely about the feedbacks.

The feedbacks dampen or reduce the direct effect of the extra CO<sub>2</sub>, cutting it roughly in half.[\[5\]](#) The main feedbacks involve evaporation, water vapor, and clouds. In particular, water vapor condenses into clouds, so extra water vapor due to the direct warming effect of extra CO<sub>2</sub> will cause extra clouds, which reflect sunlight back out to space and cool the earth, thereby reducing the overall warming.

There are literally thousands of feedbacks, each of which either reinforces or opposes the direct warming effect of the extra CO<sub>2</sub>. Almost every long-lived system is governed by net feedback that *dampens* its response to a perturbation. If a system instead reacts to a perturbation by amplifying it, the system is likely to reach a tipping point and become unstable (like the electronic squeal that erupts when a microphone gets too close to its speakers). The earth's climate is long-lived and stable— it has never gone into runaway greenhouse, unlike Venus — which strongly suggests that the feedbacks dampen temperature perturbations such as that from extra CO<sub>2</sub>.

## What the Data Says

The climate models have been essentially the same for 30 years now, maintaining roughly the same sensitivity to extra CO<sub>2</sub> even while they got more detailed with more computer power.

- How well have the climate models predicted the temperature?
- Does the data better support the climate models or the skeptic's view?

## Air Temperatures

One of the earliest and most important predictions was presented to the US Congress in 1988 by Dr James Hansen, the “father of global warming”:

Dr David Evans

Figure 3: Hansen's predictions [6] to the US Congress in 1988, compared to the subsequent temperatures as measured by NASA satellites [7].

Hansen's climate model clearly exaggerated future temperature rises.

In particular, his climate model predicted that if human CO<sub>2</sub> emissions were cut back drastically starting in 1988, such that by year 2000 the CO<sub>2</sub> level was not rising at all, we would get his scenario C. But in reality the temperature did not even rise this much, even though our CO<sub>2</sub>

emissions strongly increased – which suggests that the climate models greatly overestimate the effect of CO<sub>2</sub> emissions.

A more considered prediction by the climate models was made in 1990 in the IPCC's First Assessment Report:[\[8\]](#)

Figure 4: Predictions of the IPCC's First Assessment Report in 1990, compared to the subsequent temperatures as measured by NASA satellites.

It's 20 years now, and the average rate of increase in reality is below the lowest trend in the range predicted by the IPCC.

## Ocean Temperatures

The oceans hold the vast bulk of the heat in the climate system. We've only been measuring ocean temperature properly since mid-2003, when the Argo system became operational.[\[9\]](#) [\[10\]](#) In Argo, a buoy duck dives down to a depth of 2,000 meters, measures temperatures as it very slowly ascends, then radios the results back to headquarters via satellite. Over three thousand Argo buoys constantly patrol all the oceans of the world.

Figure 5: Climate model predictions [11] of ocean temperature, versus the measurements by Argo [12]. The unit of the vertical axis is  $10^{22}$  Joules (about  $0.01^{\circ}\text{C}$ ).

The ocean temperature has been basically flat since we started measuring it properly, and not warming as quickly as the climate models predict.

### Atmospheric Hotspot

The climate models predict a particular pattern of atmospheric warming during periods of global warming; the most prominent change they predict is a warming in the tropics about 10 km up, the “hotspot”.

The hotspot is the sign of the amplification in their theory (see Figure 1). The theory says the hotspot is caused by extra evaporation, and by extra water vapor pushing the warmer wetter lower troposphere up into volume previously occupied by cool dry air. The presence of a hotspot would indicate amplification is occurring, and vice versa.

We have been measuring atmospheric temperatures with weather balloons since the 1960s. Millions of weather balloons have built up a good picture of atmospheric temperatures over the

last few decades, including the warming period from the late 70's to the late 90s. This important and pivotal data was not released publicly by the climate establishment until 2006, and then in an obscure place.[\[13\]](#) Here it is:

## Atmospheric Warming 1979 - 1999

Figure 6: On the left is the data collected by millions of weather balloons.[\[14\]](#) On the right is what the climate models say was happening.[\[15\]](#) The theory (as per the climate models) is incompatible with the observations. In both diagrams the horizontal axis shows latitude, and the right vertical axis shows height in kilometers.

In reality there was no hotspot, not even a small one. So in reality there is no amplification – the amplification shown in Figure 1 does not exist.[\[16\]](#) Even

### Outgoing Radiation

The climate models predict that when the surface of the earth warms, *less* heat is radiated from the earth into space (on a weekly or monthly time scale). This is because, according to the theory, the warmer surface causes more evaporation and thus there is more heat-trapping water vapor. This is the heat-trapping mechanism that is responsible for the assumed amplification in Figure 1.

Satellites have been measuring the radiation emitted from the earth for the last two decades. A major study has linked the changes in temperature on the earth's surface with the changes in the outgoing radiation. Here are the results:

Figure 7: Outgoing radiation from earth (vertical axis) against sea surface temperature (horizontal), as measured by the ERBE satellites (upper left graph) and as “predicted” by 11 climate models (the other graphs).<sup>[17]</sup> Notice that the slope of the graphs for the climate models are opposite to the slope of the graph for the observed data.

This shows that in reality the earth gives off *more* heat when its surface is warmer. This is the opposite of what the climate models predict. This shows that the climate models trap heat too aggressively, and that their assumed amplification shown in Figure 1 does not exist.

## Conclusions

All the data here is impeccably sourced — from satellites, the Argo buoys, and weather balloons.<sup>[18]</sup>

The air and ocean temperature data shows that the climate models overestimate temperature rises. The climate establishment suggest that cooling due to undetected aerosols might be responsible for the failure of the models to date, but this excuse is wearing thin—it continues not to warm as much as they said it would, or in the way they said it would. On the other hand, the rise in air temperature has been greater than the skeptics say could be due to CO<sub>2</sub>. The skeptic’s

excuse is that the rise is mainly due to other forces – and they point out that the world has been in a fairly steady warming trend of 0.5°C per century since 1680 (with alternating ~30 year periods of warming and mild cooling) where as the vast bulk of all human CO<sub>2</sub> emissions have been after 1945.

We've checked all the main predictions of the climate models against the best data:

<b>Test</b>	<b>Climate Models</b>
Air temperatures from 1988	Over-estimated rise, even if CO <sub>2</sub> is drastically cut
Air temperatures from 1990	Over-estimated trend rise
Ocean temperatures from 2003	Over-estimated trend rise greatly
Atmospheric hotspot	Completely missing — no amplification
Outgoing radiation	Opposite to reality — no amplification

The climate models get them all wrong. The missing hotspot and outgoing radiation data both, independently, prove that the amplification in the climate models is not present. Without the amplification, the climate model temperature predictions would be cut by at least two thirds, which would explain why they overestimated the recent air and ocean temperature increases. Therefore:

1. The climate models are fundamentally flawed. Their assumed threefold amplification by feedbacks does not in fact exist.
2. The climate models overestimate temperature rises due to CO<sub>2</sub> by at least a factor of three.

The skeptical view is compatible with the data.

## **Some Political Points**

The data presented here is impeccably sourced, very relevant, publically available, and from our best instruments. Yet it never appears in the mainstream media – have you ever seen anything like any of the figures here in the mainstream media? That alone tells you that the “debate” is about politics and power, and not about science or truth.

This is an unusual political issue, because there is a right and a wrong answer and everyone will know what it is eventually. People are going ahead and emitting CO<sub>2</sub> anyway, so we are doing the experiment: either the world heats up by several degrees by 2050 or so, or it doesn't.

Notice that the skeptics agree with the government climate scientists about the direct effect of CO<sub>2</sub>; they just disagree just about the feedbacks. The climate debate is all about the feedbacks; everything else is merely a sideshow. Yet hardly anyone knows that. The government climate scientists and the mainstream media have framed the debate in terms of the direct effect of CO<sub>2</sub>

and sideshows such as arctic ice, bad weather, and psychology. They almost never mention the feedbacks. Why is that? Who has the power to make that happen?

## **About the Author**

*[Dr David M.W. Evans](#) consulted full-time for the Australian Greenhouse Office (now the Department of Climate Change) from 1999 to 2005, and part-time 2008 to 2010, modeling Australia's carbon in plants, debris, mulch, soils, and forestry and agricultural products. Evans is a mathematician and engineer, with six university degrees including a PhD from Stanford University in electrical engineering. The area of human endeavor with the most experience and sophistication in dealing with feedbacks and analyzing complex systems is electrical engineering, and the most crucial and disputed aspects of understanding the climate system are the feedbacks. The evidence supporting the idea that CO<sub>2</sub> emissions were the main cause of global warming reversed itself from 1998 to 2006, causing Evans to move from being a warmist to a skeptic.*
